### Abstract

The most effective stabilizer for zirconium oxide is yttrium oxide. However, the structure of  $\text{Y-ZrO}_2$  degraded at low temperature. Partial substitution of  $\text{Fe}^{3+}$  for  $\text{Y}^{3+}$  in system  $\text{Y}_2\text{O}_3\text{-ZrO}_2$  decreases both the crystallization and sintering temperature of zirconia ceramic. It is known that the content of monoclinic (M), tetragonal (T) and cubic (C) polymorphs determines the properties of  $\text{ZrO}_2$ .

The aim of present work is the investigation of structural peculiarities (polymorphs, positions of atoms, site occupancies, local environment of  $\text{Fe}^{3+}$ ) of zirconium oxide stabilized by combined dopant ( $\text{Y}_2\text{O}_3$  and  $\text{Fe}_2\text{O}_3$ ) depending on chemical composition ( $(1-x)\text{ZrO}_2 \cdot x\text{Y}_2\text{O}_3 \cdot y\text{Fe}_2\text{O}_3$ , where  $x + y = 0.03\text{-}0.08$ ), synthesis conditions (coprecipitation of hydroxides or successive precipitation of hydroxides) and heat treatment (970-1570 K).

It has been shown that solubility of iron in  $\text{Y-ZrO}_2$  increases with yttrium content. Iron dissolves completely in  $\text{Y-ZrO}_2$  at  $\text{Y/Fe} \geq 2$ . Increasing  $\text{Y/Fe}$  ratio in  $\text{ZrO}_2$  doped with the same total amount of doping oxides stabilizes the structure and inhibits low-temperature degradation. Increasing the total amount of doping oxides extends the temperature range of existence of C and C + T polymorphs of  $\text{ZrO}_2$ . Mossbauer spectra of fully stabilized tetragonal  $\text{Y-Fe-ZrO}_2$  showed that distribution of  $\text{Fe}^{3+}$  ions has a cluster topology. Two nonequivalent sites of  $\text{Fe}^{3+}$  with octahedral coordination in coprecipitated samples and three nonequivalent sites of  $\text{Fe}^{3+}$  with octa-, penta- and tetrahedral coordination in successively precipitated samples have been identified. Decrease in coordination number of iron ions in comparison with that of host cations in  $\text{Y-ZrO}_2$  stabilizes the structure and inhibits its degradation due to increase in Me-O binding energy. It has been shown that precipitated  $\text{ZrO}_2$  powders contain nanoparticles with grain size of 10-20 nm. Successiv
